## Utilitarian and Approval Voting

## Jean-Francois Laslier, CNRS and Ecole Polytechnique, Paris with A. Baujard, A. Blais, F. Gavrel, H. Igersheim, M. Nunez I. Lebon, N. Sauger, K. Van der Straeten

#### Oxford, April 2013

< - 12 →

#### Public and scientific debates on voting methods.

- A public discussion on voting rules :
  - The 2002 French presidential election surprise : "tactical vs. true voting" becomes an issue.
  - Canadian (BC) Citizen Assembly on Electoral Reform 2004
  - UK referendum 2011
- Some theoretical results :
  - Background : classical SCW results about utilitarianism (Arrow and followers, D'Aspremont, Gevers)
  - Limits of one-round and two-round systems : Condorcet criterion, manipulability, non-participation...
  - Properties of pluri-nominal voting rules (especially Approval) : other kind of strategic voting, higher probability of electing the Condorcet's winner...

< D > < P > < P > < P >

# Research agenda : Comparing voting rules regarding voter's behavior and who is elected

Restrict attention to elections of the "presidential" type : one candidate to be elected. Leave aside proportional rule.

Consider as fixed the set of candidates, and their platforms : do not compare rules with respect to the induced electoral competition.

Consider specific rules : simple plurality (1R), two-round majority voting (2R), alternative vote (Single Transferable Vote : STV), approval voting (AV), evaluative voting (EV), Borda rule...

## Research questions

Received ideas :

- IR plurality kills third candidates (electoral competition?)
- 2 R majority favors divisive candidates and kills centrists
- AV and EV would favor consensual candidates

Why?

- mechanical effects (counting ballots)
- Psychological effects (filling ballots)

Utilitarianism Strategy

## Theory background : The axiomatics of utilitarianism

## Interpersonal comparisons of utility, utilitarianism

Start from a framework where individuals utilities are represented by real numbers  $U_i = U = \mathbb{R}$ . Let n = |I| denote the number of individuals in the society. A utility-profile is a vector

## $u \in \mathbb{R}^{I}$

We look for a *social-evaluation ordering*, that is a complete pre-order of  $\mathbb{R}^{I}$ . All Arrow's properties will be satisfied (neutrality, anonymity, rationality, independence of irrelevant alternatives, no domain restriction) but we allow ourselves more information as input for collective judgement, which opens possibilities for performing such a judgment. For instance we now can discuss the possibility of adding utilities.

Utilitarianism Strategy

7

Let  $\succ$  denote the collective preference,  $\succ$  is a **generalized utilitarianism** iff there exists a continuous increasing real-valued function g such that :

$$u \succcurlyeq v \iff \sum_{i \in I} g(u_i) \ge \sum_{i \in I} g(v_i)$$

The collective preference then satisfies four properties :

The anonymity requirement.

**Strong Pareto** : If  $u_i \ge v_i$  for all *i*, with at least one strict inequality then  $u \succ v$ .

**Continuity** For all  $u \in \mathbb{R}^{l}$  the sets  $\{v \in \mathbb{R}^{l} : v \succcurlyeq u\}$  and  $\{v \in \mathbb{R}^{l} : u \succcurlyeq v\}$  are closed in  $\mathbb{R}^{l}$ .

Utilitarianism Strategy

8

Independence of the Vote of Unconcerned Individuals. For any subset  $J \subseteq I$  of individuals and vectors u, v, u', v' such that  $u_j = v_j$  and  $u'_j = v'_j$  for all  $j \in J$  and  $u_i = u'_i$  and  $v_i = v'_i$  for all  $i \in I \setminus J$ , one has :  $u \succcurlyeq v \iff u' \succcurlyeq v'$ .

In fact these properties together characterize generalized utilitarianism.

**Generalized Utilitarianism Theorem** : For three or more individuals, a social-evaluation function satisfies Anonymity, Strong Pareto, Continuity, and Independence of Unconcerned Individuals if and only if it is a generalized utilitarianism.

< ロ > < 同 > < 回 > <

Utilitarianism Strategy

8

Independence of the Vote of Unconcerned Individuals. For any subset  $J \subseteq I$  of individuals and vectors u, v, u', v' such that  $u_j = v_j$  and  $u'_j = v'_j$  for all  $j \in J$  and  $u_i = u'_i$  and  $v_i = v'_i$  for all  $i \in I \setminus J$ , one has :  $u \succcurlyeq v \iff u' \succcurlyeq v'$ .

In fact these properties together characterize generalized utilitarianism.

**Generalized Utilitarianism Theorem** : For three or more individuals, a social-evaluation function satisfies Anonymity, Strong Pareto, Continuity, and Independence of Unconcerned Individuals if and only if it is a generalized utilitarianism.

#### Bentham Utilitarianism

The most important example of generalized utilitarianism is the simple sum :

$$u \succcurlyeq v \iff \sum_{i \in I} u_i \ge \sum_{i \in I} v_i$$

which corresponds to the identity function for g or to any increasing affine g. This is just called "utilitarianism," or sometimes "classical," "pure," or "Bentham" utilitarianism

A characteristic feature of (classical) utilitarianism is Cardinal Full Comparability. This is the requirement that social evaluation is invariant with respect to any increasing affine transformation of individual utility (affine equivalence at the individual level) if the same affine transformation is applied to all individuals (inter-personal comparability).

Utilitarianism Strategy

10

**Cardinal Full Comparability**. For any numbers a > 0 and b,

$$u \succcurlyeq v \iff (a \cdot u + b) \succcurlyeq (a \cdot v + b)$$

**Classical Utilitarianism Theorem**. For three or more individuals, a Social-evaluation function satisfies Anonymity, Strong Pareto, Continuity, Independence of Unconcerned Individuals and Cardinal Full Comparability if and only if it is classical utilitarianism.

Utilitarian comparisons remain unchanged if the constant *b* is not independent of individuals. Utilitarianism needs not to compare absolute utility levels for different individuals but only utility differences.

## Social substitutes.

The question on debate : Two individuals are substitutes with respect to the production of social welfare. Let  $W = \sum_{i \in I} g(u_i)$ ,  $dW = \sum_{i \in I} g'(u_i) du_i$ . The marginal rate of substitution between *i* and j's utility is :  $\frac{g'(u_i)}{g'(u_i)} = 1$  for Bentham. Notice these mathematics can receive two interpretations : 1. We know the true level  $u_i$  of i's utility, and social rates of substitutions depend on utility levels. 2.  $u_i$  is not utility but a proxy (ex : money) and all individuals have the same utility function g (ex : log), and social rates of substitutions do not depend on utility levels.

For Voting theory : Sincere statements, comparable among individuals, with rates of substitutions independent or not of utility levels.

Utilitarianism Strategy

## Theory background : strategy

If ballots and isomorphic to preferences, Gibbard and Satterthwaite : impossible to guarantee that truth-telling is a dominant strategy. A very robust statement but a too strong concept ?

Two questions : What are good strategies ? What are the equilibria ?

For Evaluative Voting, a folk conjecture : "overstating" preferences. Nunez and Laslier (SCW forthcoming)a counter-example with 7 voters and 3 candidates, compatible with single-peaked preferences. A perfect equilibrium, the unique best-response of a voter is not overstating.

Utilitarianism Strategy

## Theory background : strategies

Politics : with many voters, different models to tackle the problem of the multiplicity of Nash equilibria since Myerson and Weber (APSR 1993). These are ad hoc refinements for voting games.

*Approval* : Laslier (J Th Pol 2009) Strategy = rational response to almost perfect pools. Best response correspondence easy to describe. Pure equilibrium if and only if there exists a Condorcet candidate, in which case she is elected.

*Evaluative* : Nunez and Laslier (SCW forthcoming) : as suggested by intuition, rational voters overstate their evaluations, various evaluative rules are strategically equivalent.

*Two-round majority* : Van der Straeten and Laslier (in progress)the best response correspondence is difficult to describe.

## Voting rules in the lab.

Participants are voters, candidates are letters, or colors. Participants are paid depending on which candidate is elected.

Seminal paper : Forsythe, Rietz, Myerson, Weber "An Experiment on Coordination in Multicandidate Elections : the Importance of Polls and Election Histories" *Soc. Ch. Welf. 1993*.

Study 1R, Approval, and Borda, with 3 candidates. Illustrates strategic voting as desertion of non-viable candidates in a split-majority situation. Points an inefficiency of 1R voting.

What follows based on Blais, Laslier, Sauger, Van der Straeten "Sincere, Strategic, and Heuristic Voting under four Election Rules : An Experimental Study" *Soc. Ch. Welf. 2010*.

Design Results

## Lessons from lab. expe.

- Voters vote strategically when the strategic reasoning is not too complex.
- Otherwise they vote according to some heuristics, including sincere voting.
- This may imply important effects of pools and history.
- Voting rules matter and induce important differences in result/behavior

All this is subject to the external validity critique. Here : you did all what you could to induce the participants to behave strategically, in particular by paying them.

(日) (同) (三) (三)

## Which candidate is favored by each voting rule?

#### Two kinds of candidates

Divisive candidate Candidate inducing strong views, whichever positive or negative, is not necessarily extreme, whose support relies on one specific part of a fragmented society

Consensual candidate Unifying candidate, eventually positively considered by a large fraction of the voters, whose support comes from different part of the society

## Which candidate is favored by each voting rule?

Arguments to explain WHO (i.e., which type of candidates) is favored by which voting rules and WHY. Here, we show that :

- **1** 2R favors divisive candidates
- AV and EV favor consensual candidates

Design Results

## Conclusion on In Situ experiments

#### Observed features :

- 2R favors divisive candidates
- AV and EV favor consensual candidates

#### Reasons :

- Under 1R and 2R, strategic voting favors strong candidates.
- Plurinominality favors consensual candidates in AV-EV because of expressive voting

#### On the method :

- Participants do their job very seriously
- But half of them do not want to state explicitly their true vote
- We cannot ask for more than a few minutes

## The Vote Au Pluriel web site

The "Popular Science" part of a large Canadian-funded research project. Realized in Ontario, France, Iceland, Quebec. Offers information about how people vote in different countries. Visitors invited to try themselves for the current election. An optional questionnaire at the end.

#### France 2012

- presents four rules : 1R (Mexico), 2R (Fr.), Alternative Vote (Ireland), Approval (nowhere)
- Open 3 weeks prior to election day
- More than 20 000 visitors, 11 000 cast all votes, 8 044 with questionnaires

## Who wins and loses

#### Internet confirms the observations in the lab and In Situ

- 1R and 2R kills small candidates,
- Approval and Evaluative Voting favors the extremes as to the apparent relative strength,
- and favors the center as to the probability of winning.

This three-fold confirmation is also a confirmation that those un-orthodox methods are consistent hence meaningful.

Design Results

## Preferences and votes under four voting rules

"Do you always vote for the candidate you wish to see elected ?" 30% say "No"

Candidate	Prefer.	2R (*)	1R	AV 1st	Appr.

## Preferences for candidates and rules

The internet method is less intrusive and allows more detailed questionnaires. Participants seem to be looking for expressive modes of elections. We asked the voters which rule they prefer/dislike.

- Are preferences over rules related to political opinions? Yes.
- Do we observe self-serving preferences? Not exactly.

	Alternative Vote	Approval	1R	2R	missing	total	percentage of weighted observations	Number of observations

## Preferences for candidates and for rules

55

There seem to be two combined effects :

- Supporters of small candidates prefer evaluations. Can be interpreted as self-serving preferences, especially given the recurring debate about the voting system and proportional representation.
- Conservative voters prefer single-name ballots, left-wing voters prefer evaluations. An ideological effect independent of the previous one.

This last observations may inform us on the political psychology and the nature of political preferences.
